1.1 SITE NAME AND LOCATION

Cameron Station
Alexandria, VA
Operable Units 1, 3, 4, 5, 6, and 8

1.2 STATEMENT OF BASIS AND PURPOSE

This Decision Document (DD) identifies the selected methods for remediating Cameron Station, a military installation located in Alexandria, Virginia slated for closure by September 1995. This document is issued by the U.S. Army Environmental Center (USAEC). Though this site is not a CERCLA site, the Army has chosen to perform CERCLA-style evaluations of sites slated for closure and transfer from federal government ownership. The investigations performed and documents prepared for this site have been issued generally in accordance with the CERCLA process. This DD, therefore, corresponds to a Record of Decision (ROD) that would have been issued had this actually been a CERCLA site. The information supporting the lead and support agencies' decisions on the selected remedies is contained in the administrative record.

1.3 ASSESSMENT OF THE SITE

Actual or threatened releases of hazardous substances from this site, if not addressed by implementing the response actions selected in this DD, may present an imminent and substantial endangerment to public health, welfare, or the environment.

1.4 DESCRIPTION OF THE REMEDY

The installation was investigated and remedial actions were evaluated in the Remedial Investigation and Feasibility Study (RI/FS) performed from August 1990 through December 1992. Twelve Operable Units (OUs) or potential sources/areas of contamination were investigated. Only six OUs (OUs-1, 3, 4, 5, 6, and 8) were found to warrant remediation. No further action is necessary for the remaining six OUs. The response actions in this document address the principal threat at the site by treating contaminated soils and groundwater identified

at these OUs. Contaminated groundwater will be treated on-site. Contaminated residuals and soils will be disposed of off-site, such that the site will not require any long-term management subsequent to remediation. The major components of the selected remedy include:

- OU-1 Excavation of approximately 10 cubic yards of PCB and pesticide-containing material and disposal at an off-site RCRA Subtitle C landfill.

- OU-3 Soil capping and monitoring of the approximately 20,000 square foot landfill. The cap will be designed to meet the state requirements for the closure of unpermitted construction/demolition/debris landfills.

- OU-4 Excavation of approximately 20 cubic yards of pesticide-containing wastes around the Building 30 septic tank, removal of the septic tank, and disposal at a RCRA Subtitle C landfill.

- OU-5 Groundwater collection followed by air stripping and discharge to surface water (with carbon treatment of air discharge) of TCE and 1,1-DCE contaminated groundwater near Building 2.

- OU-6 Excavation of approximately 10 cubic yards of TPHC and metal contaminated soils from two acid pit locations for disposal in an off-site RCRA permitted thermal treatment facility. Metals in the ash will be solidified before disposal.

- OU-8 Groundwater collection followed by air stripping and in-situ bioremediation of BTEX contaminated groundwater near the Building 2 and the PX service station.

1.5 STATUTORY DETERMINATIONS

The selected remedy is protective of human health and the environment, complies with Federal and State requirements that are legally applicable or relevant and appropriate to the remedial actions, and is cost effective. This remedy utilizes permanent solutions and alternative treatment (or resource recovery) technologies to the maximum extent practicable and satisfies the statutory preference for remedies that employ treatment that reduces toxicity, mobility, or volume as a

principal element. Because this remedy will not result in hazardous substances remaining on-site above health based levels, the five-year review will not apply to these actions.

2.1 SITE NAME, LOCATION, DESCRIPTION, HISTORY AND ENFORCEMENT ACTIONS

Cameron Station is an Army installation located within the city limits of Alexandria, Virginia, approximately 2 miles west of downtown Alexandria and 1 mile east of the Interstate 395 and Virginia Route 236 interchange in Fairfax County (Figure 2-1). The 164-acre facility is bordered to the south and east by Backlick Run and Holmes Run, respectively. These streams converge at the southeastern portion of the installation to form Cameron Run, a tributary to the Potomac River. A Southern Railway right-of-way parallels Backlick Run and separates Cameron Station from Cameron Run Valley West, an industrial area located south of the installation. The Installation is bordered to the west and northwest by mixed commercial, residential, and industrial developments. Duke Street (Route 236) forms the northern boundary of the site.

Cameron Station has not been associated with weapons manufacture, chemical or otherwise, or heavy industrial activity. The site currently serves primarily as office space for civilian employees of several governmental agencies and has a Commissary and Post Exchange serving a large active and retired military population. Cameron Lake, consisting of interconnecting North and South Ponds, is located in the eastern portion of the site.

Service and storage facilities comprise about 40 percent of the total land use. Administration and community facilities make up about 26 percent and 11 percent of the land use, respectively. Recreational use covers 23 percent and medical use is less than 1 percent of the installation. The post includes 29 permanent buildings totaling 1,299,871 square feet, and four temporary buildings totaling 9,444 square feet. Cameron Station is primarily an administration facility. Most of the warehouse space has been converted to office space or commissary and PX facilities. The primary site features are shown on Figure 2-2.

Alexandria had a population of approximately 109,000 in 1988 (USACE, 1991). In 1985, about 61,000 people lived within a 2-mile radius of the installation. The Landmark-VanDorn planning area surrounding Cameron Station contains almost 1,065 acres, of which 25% is residential, 25% is industrial, 10% is parkland or vacant land, and the remainder is in office or retail use. The Cameron Station site was originally wetlands. The topography of Cameron Station now

ranges in elevation from about 45 to 85 feet above mean low water (ICF, 1990a). As a consequence of grading and of the construction of storm water drainage structures, approximately 97 percent of the site is now within the 100-year floodplain.

CAMSTA occupies land that was part of a vast pre-Revolutionary estate belonging to the Right Honorable Thomas Lord Fairfax, Baron Cameron. Gradually, the land was divided into smaller farms and mills. Soon after the beginning of World War II in 1942, 12 tracts of land consisting of approximately 164 acres were deeded to the government by purchase and condemnation for a general depot. The original designation of the installation was the Alexandria Quartermaster Depot, a Class II installation operated by the Quartermaster General. One of the responsibilities of the Quartermaster Department, dating back to 1869, was the operation of commissaries and PXs. In 1950, control of the facility was transferred to the Military District of Washington (MDW), and the depot was redesignated Cameron Station. In 1954, it became a permanent Department of the Army installation. Most of the warehouses were divided into office space in 1962, and the headquarters of the Defense Supply Agency (later redesignated the Defense Logistics Agency) was established at the installation. With the 1971 reorganization of the MDW, the post staff was eliminated and most of the MDW functions were moved to CAMSTA. Review of historical aerial photographs over the period 1949 to 1966 revealed that Cameron Station was surrounded by a rural/suburban environment in 1949. At that time, the majority of the site structures described above were present, with the exception of Building 23. Cameron Lake did not appear in the 1949 photograph, nor was there any evidence of base activity south of Backlick Run. Cameron Lake appears in the 1966 photograph as two adjacent but separate ponds. At that time activity is evident south of Backlick Run in the area now referred to as the "Landfill". The 1966 photograph also shows both the present PX service station (Building 23) and the previous PX service station, which was located north of Building 1.

Several investigations into environmental quality have been performed at Cameron Station during its history. Some of these studies were performed as a routine management action, and some were in response to a specific event (e.g., a spill). Each of the following such studies are summarized in detail in the RI Report.

A Solid Waste Management Consultation (No. 26-0466-77) was conducted at CAMSTA in September 1976 by the U.S. Army Environmental Health Agency (USAEHA) to evaluate the disposal of pesticide rinsewater and to investigate the possibility of groundwater and soil contamination from septic tank disposal operations. In July 1977, an Installation Pest

Management Program Survey (IPMPS No. 61-0540-78) was conducted by the USAEHA to evaluate the installation pest management program. An Installation Pest Management Program Review (No. 16-61-0535-82) was conducted in January 1982 by USAEHA to examine the existing pest management program. The primary emphasis of the review was on the program's health, safety, and procedural aspects as well as on specific areas identified in the IPMPS of July 1977. A Pesticide Monitoring Survey (No. 17-44-0252-85), was performed in September 1984 by USAEHA to evaluate the distribution of pesticides in several land use areas and major surface water systems. In May 1989, USAEHA conducted a Pesticide Risk Management Consultation (No. 17-38-0026-89) to investigate pigeon problems in and around Building 21.

In July 1983, a Hazardous Waste Management Survey (No. 37-26-0304-84) was conducted by USAEHA to review management of hazardous waste relative to the requirements of the Resource Conservation and Recovery Act (RCRA) of 1976, as amended, and applicable State and local requirements. An installation assessment of CAMSTA was conducted in 1984 by Environmental Science and Engineering (ESE, 1984) for the Army Environmental Center. The purpose of this assessment was to determine the presence of any toxic or hazardous materials and to assess the potential for off-post migration. The investigation consisted of a records search, interviews with current and former employees, and an on-site investigation of environmentally significant areas. An enhanced Preliminary Assessment of CAMSTA was performed and a report prepared in 1989 by Argonne National Laboratory for the Army Environmental Center. The purpose of the assessment was to address all documented or suspected incidents of actual or potential releases of hazardous or toxic constituents to the environment. The investigation consisted of a review of property files, interviews with employees, a site visit, and direct observation.

On August 30, 1979, a PCB spill occurred at CAMSTA in front of Door #17 outside of Building 9. Approximately three gallons of PCB fluid spilled from a damaged transformer onto a wooden truck bed and the underlying asphalt parking area. The spill was cleaned up, and the asphalt in the spill area removed. In June 1989, approximately 30 gallons of diesel fuel were spilled between Buildings 5 and 6. Much of the fuel ran into storm sewers 140, 143, and 163 which drain into Backlick and Cameron Runs. The Alexandria HAZMAT team contained much of the spill, but before cleanup was completed, a rainstorm washed the remaining fuel down Cameron Run. Several spills of gasoline have reportedly occurred at the PX Service Station (Building 23) over time. No documentation of individual spills is available. Base personnel indicate that on several occasions, tank overfills resulted in small releases (up to 50 gallons). Additionally, facility personnel reported that at least one fiberglass tank required repair some time in the 1980s

after the tank bottom was found to be punctured. Details of the leak, such as the duration, quantity, amount of material recovered, etc., are not known. Early in the RI, free-phase petroleum product and dissolved petroleum contamination of groundwater was discovered at the PX service station, and a limited amount of free product was observed at a No. 2 fuel oil tank at Building 2. In June 1991, an Interim Remedial Action (IRA) was initiated to address this problem in accordance with Virginia Regulation 680-13-02, Sections 6.4 and 6.5. A Site Characterization Report and Corrective Action Plan have been submitted to the state in accordance with Virginia regulations.

2.2 HIGHLIGHTS OF COMMUNITY PARTICIPATION

The Proposed Plan was distributed to solicit public comments regarding the proposed remedial alternatives for contaminated soil and groundwater at Cameron Station. USAEC relies on public input so that the remedy selected for the site meets the needs and concerns of the local community. To assure that the community's concerns were addressed, a public comment period was in effect from March 4 through May 3, 1993 and the opportunity for a public meeting to be held in the community was offered. The community did not request such a meeting. It is important to note that although USAEC selected preferred alternatives in the Proposed Plan, no final decision was made until after the comment period ended and all comments were considered. The Army solicited comments on all remedial alternatives evaluated in the FS and summarized in the Proposed Plan. Comments received are presented and responses provided in the Responsiveness Summary (Section 3.0) of this document.

2.3 SCOPE AND ROLE OF THE BASE CLOSURE RI/FS

The U.S. Army Environmental Center (USAEC) performed a Remedial Investigation and Feasibility Study (RI/FS) at Cameron Station in support of the base-closure process. It should be noted that Cameron Station is not a Superfund site. The Army has chosen to perform CERCLA-style evaluations of sites slated for closure and transfer from federal government ownership, however, and therefore the RI/FS was performed generally in accordance with the CERCLA process.

The RI/FS was performed from August 1990 through December 1992. Twelve OUs, or potential sources/areas of contamination, were investigated at Cameron Station. Each OU was investigated during the RI to define the nature, magnitude, and extent of any environmental

contamination. Information obtained from the RI was used during the FS to assess the health and environmental risks associated with closure and transfer of the base; to determine the necessity for remedial actions; and to develop and evaluate remedial action alternatives.

Based on the results of the RI/FS, only six OUs (OUs-1, 3, 4, 5, 6, and 8) were found to warrant remediation. A Proposed Plan, which contains remedial alternatives considered and identifies preferred alternatives, was prepared and made available for public comment.

The information repository that contains the RI and FS reports, the Proposed Plan, this Decision Document, and supporting documentation is available at the following location:

Alexandria Library
Ellen Coolidge Burk Branch
4701 Seminary Road
Alexandria, Virginia 22304

A glossary of terms that may be unfamiliar to the general public is provided in Appendix A.

2.4 SUMMARY OF SITE CHARACTERISTICS

This section provides an overview of each of the six operable units to be remediated. The following is a brief discussion of contaminants of concern, concentrations of contaminants, and media affected at each of these operable units. Descriptions of risks and routes of human and environmental exposures are presented in Sections 2.5, 2.6 and 2.7.

2.4.1 Operable Unit 1 - PCB Transformers

The use, storage and past spill of PCB transformers at Cameron Station have not resulted in widespread contamination. Based on the results of the Remedial Investigation, only highly localized, very low-level PCB contamination (1.24 mg/kg) of asphalt exists behind Building 9 (sample PCB 095). Although PCBs were detected (up to 55.04 $\mu g/100\ cm^2$) in the asphalt at the location of the spill documented at Door 17 of Building 9, no PCBs were found in the soil beneath the asphalt. The highest level of PCBs detected on the asphalt (55 $\mu g/100\ cm^2$ is less than the regulatory level for surficial contamination in restricted areas (100 $\mu g/100\ cm^2$) such

as the fenced area behind Building 9. This exceeds the unrestricted-access area standard of 10 $\mu g/100\ cm^2$, however.

Although asphalt at the storage areas may contain some PCBs, detection of only 1.24 mg/kg PCB in only one of the fifteen asphalt samples taken suggests only highly localized low concentrations of PCB. The detection of 2.12 mg/kg PCBs in surficial soils just off the asphalt storage area is further evidence that significant PCB contamination does not exist in this area (the regulatory level for cleaning up spill-contaminated soil is 10 mg/kg). Finally, significant PCB contamination was not found at pole or platform transformer locations by detecting PCBs in only four soil samples, all at levels less than 1 mg/kg. Although significant PCB contamination does not exist, remediation is being proposed since the site will be made available for unrestricted use.

2.4.2 Operable Unit 3 - Landfill

The results of the investigation into the landfill operable unit (OU) do not suggest widespread contamination of the subsurface soils or groundwater. Visual observations during the RI indicate that wastes normally associated with sanitary landfills (paper, household food wastes and debris, glass bottles and metal cans) are not present at the locations investigated. Methane gas was not observed during landfill boring activity. Furthermore, no leachate seeps have been observed at any time along the banks of the landfill at Backlick or Cameron Runs.

The soil within the interpreted limits of the landfill was found not to contain the majority of constituents analyzed. Only cadmium (at 1.17 mg/kg) and silver (at 5.71 mg/kg) in one sample exceeded the common range of concentrations for natural soils. This sample also contained a number of PAHs that totaled approximately 630 mg/kg and are attributed to wooden debris encountered at the depth of that sample. The isolated detections of PAHs in the landfill soil borings indicate that these compounds are not uniformly distributed in the fill. Both the metals and the PAHs appear to be relatively immobile under the conditions encountered as evidenced by the absence of PAHs, silver and cadmium in groundwater sampled from each well in this OU. Some metals were observed in shallow groundwater at greater than ambient conditions, but the deep groundwater is not impacted. Although widespread contamination was not identified, remedial action consisting of capping the landfill is being proposed to minimize the potential for future impacts to groundwater.

2.4.3 Operable Unit 4 - Pesticides Use and Storage Areas

Pesticides and their associated by-products (dioxins) are present in soil, sludge and groundwater at the site. In some locations, the concentrations of pesticides are very low, reported at levels just above the detection limits. Results for soils as well as PCB wipes analyzed for pesticides show low levels (less than 1 mg/kg) of these chemicals across the site. This would be expected where the chemicals have been routinely applied. It is likely that similar concentrations exist in soils in surrounding off-site areas where similar products are applied.

Only two localized areas of elevated pesticides have been identified: The area behind Building 9 at Door 17, where DDT ranged up to 35 mg/kg (sample PCB 09S5) in soil beneath asphalt; and the area near Building 30 where DDT was reported at 12 mg/kg (samples SB13). The concentration of a pesticide in groundwater (heptachlor at 0.016 μg/L) exceeds the state standard (0.001 μg/L), but only slightly, at the location of the Building 30 septic tank.

The concentrations of dioxins in soils detected across the site are not unexpected given the history of pesticide application. The levels of dioxins present in the fence line soil samples SOFL13, SOFL14, SOFL19 and SOFL21 are elevated compared to the other site concentrations and reported urban-area concentrations. The level of 2,3,7,8-Dioxin detected in the fence line samples (up to 0.9 μg/kg) is lower than the cleanup level set by U.S. EPA Region VII for dioxin contaminated Superfund sites (1 μg/kg).

The presence of the Building 30 septic tank creates the potential for contaminant releases to the groundwater to occur, as evidenced by the presence of the pesticides in groundwater in this area.

2.4.4 Operable Unit 5 - Sanitary and Storm Sewer Systems

The contents of some sewer system features, such as the Building 5 sludge tank and Building 9 grease trap, represent potential sources of contamination if demolition of the sewer systems causes releases to the environment. Sludge tanks and grease pits in the sewer system have been cleaned out since the RI was conducted. The presence of TCE in the storm sewer water and the storm sewer outfall into Cameron Lake may have been caused by past discharges from Cameron Station activities, however the discharges have ceased.

Solvent contaminated groundwater (primarily TCE) was found in MWS15 in concentrations as high as 500 μg/L near Building 2. The level of TCE exceeds the MCL of 5 μg/L. Other contaminants, including 1,1-DCE which exceeds its respective MCL, are also present in the groundwater at this location.

A separate area of benzene and 1,2-DCA in groundwater was identified extending across the site from the western property boundary eastward approximately to Building 7. Detected levels of benzene ranged up to 800 μg/L in this area (MWS26) which exceeds the MCL of 5 μg/L. The source of this contamination appears to be off-site, based on the ground water flow direction and the existence of this contamination at the upgradient property boundary. An alleged release from an underground storage tank located upgradient from Cameron Station is a possible source of this contamination, although no details concerning the potential off-site source have been made available by cognizant regulatory agencies. Remediation of contamination apparently originating off-site was not addressed in the FS because the source of contamination is beyond the Army's control, and remedial alternatives cannot be identified, screened or analyzed without first defining the source conditions. The installation has notified state and Federal agencies of this situation and will cooperate in efforts as required. Any potential future cleanup that may be required for this contamination will be addressed in a separate ROD.

2.4.5 Operable Unit 6 - Acid Pits

Petroleum waste may have been placed in the acid pit located at Building 23, the PX service station, however it is difficult to evaluate this due to widespread contamination at that site caused by the releases from the fuel tanks. At Building 9, the results from the acid pit soil sample indicate disposal of petroleum as well as lead-containing wastes. The effects of the acid pit disposal, however, appear to be isolated since no chemical contamination was detected in MWS12, located less than 50 feet downgradient from the Building 9 acid pit. TPHCs were found at up to 21,000 mg/kg, and lead at of 4,200 mg/kg.

2.4.6 Operable Unit 8 - PX Service Station and Building 2 Underground Storage Tanks

The RI and subsequent Interim Remedial Action (IRA) have identified significant soil and groundwater contamination at the PX service station from releases of petroleum products. Petroleum product was observed floating in the groundwater surface in thicknesses ranging up to several feet at some locations. The heterogeneous nature of the fill soils in this area and the

likelihood that more than one significant petroleum release has occurred over time explains the irregular distribution of product in the subsurface. The PX Service Station has been closed; all USTs have been emptied and are being removed. Based on evaluations in the RI Report, the product is estimated to be present over an area of approximately 80,000 square feet extending from the PX Service Station south across Parking Lot 2. A very localized occurrence of No. 2 fuel oil is present in the immediate vicinity of the Building 2 UST. The area of petroleum product in the soil at Building 2 is estimated at less than 400 square feet. The Building 2 UST and surrounding soil has been excavated and disposed off-site.

The IRA was initiated in June 1991 to comply with Virginia Regulation 680-13-02, Sections 6.4 and 6.5. The IRA included additional site characterization studies and efforts to remove petroleum hydrocarbons from the subsurface. IRA activities are being performed in concert with the RI/FS activities.

Several monitor wells installed within the PX service station have been used as petroleum product recovery wells. Approximately 2,000 gallons of product have been recovered to date. Product recovery through recovery wells and soil vapor extraction were cleanup remedies implemented at the PX Service Station in 1991-1992 as part of the IRA.

Groundwater contamination has resulted from petroleum releases at the PX service station USTs. Concentrations of benzene up to 2,800 μg/L exceed the MCL of 5 μg/L throughout an estimated area of approximately 150,000 square feet. The contamination does not extend to the downgradient property boundary. Groundwater may have been impacted in the vicinity of the Building 2 UST, however, chemicals of concern (BTEX) have not been detected at monitor well B2-1 located 75 feet downgradient from the UST. Clay soils underlying the tank appear to have minimized the impacts of this release.

2.5 SUMMARY OF SITE RISKS

2.5.1 Risk Assessment

No noncancer health effects are expected from exposure to potentially site-related chemicals. However, exposure to site-related chemicals may result in excess cancer risks in exposed populations. These risks are likely to be overestimated due to inherently conservative

assumptions in the risk assessment. Cancer risks are very small numbers, so they are expressed in exponential notation, i.e., a one in a million cancer risk is stated as a risk of 1×10^{-6} or 1E-6.

The excess cancer risk to current children eating fish from Cameron Lake could be as high as 4E-5. This risk is due almost entirely to PCB-1260 (3E-5), with smaller contributions from dioxins (1E-5) and gamma chlordane (1E-6) in fish. The Food and Drug Administration's tolerance level for PCBs in fish is 2 mg/kg, approximately ten times the level detected in Cameron Station fish. Cancer risk estimates may also be high based on the assumption that the child eats sixty percent of two, three-pound fish (all of the edible portion of each fish he or she catches).

Current maintenance workers that come in contact with fenceline soil containing dioxins may experience an excess cancer risk as high as 2E-6 from dermal contact with this soil.

Future child residents may experience excess cancer risk as high as 7E-5. This population may experience a cancer risk from fish consumption (4E-5) similar to that of current child visitors that eat fish caught during the Cameron Lake fishing derby. Future adult and child residents may also experience risks as high as 3E-5 through ingestion of contaminated yard soil. Beryllium, dieldrin, dioxins, heptachlor, and PCB-1260 are the primary sources of this cancer risk. Dioxins and PCB-1260 are estimated to pose a total excess cancer risk of 6E-6 in future child residents exposed to yard soil by the dermal route.

Ingestion of soil during visits by future child residents to the landfill may results in an excess cancer risk as high as 1E-6 from exposure to beryllium and benzo(a)pyrene.

Future resident adults may experience an excess cancer risk as high as 3E-5 from ingestion and dermal contact with contaminated yard soil. Most of this risk is contributed by dioxins through dermal contact with soil.

Beryllium appears to be present in soil at concentrations that represent ambient conditions. Therefore, it is uncertain that risks due to exposure to beryllium in soil are site-related. All other estimated excess cancer risks appear to be site-related.

Although the baseline risk assessment was done in a conservative manner, and the above risks were identified, remediation would not be required by USEPA under current guidelines for a

Superfund site. Risks in the range of 1E-4 to 1E-6 are considered by the EPA risk managers, taking into account site specific factors, but they do not warrant remediation. Risks greater than 1E-4 require remediation. On this basis, no risk-driven remediation of the site is warranted.

2.5.2 Ecological Assessment

An ecological assessment focussing on aquatic environments found significant aquatic resources in Cameron Lake and possibly the adjacent surface water features. No rare, threatened, or endangered species or suitable habitat for these species were found to be present on Cameron Station. Levels of some metals and PAHs in Cameron Lake sediment, and some metals in Cameron Lake and adjacent surface waters, could cause adverse effects on aquatic biota. Fish in Cameron Lake were found to contain some potentially site-related compounds; however, this represents very low levels of uptake from sediments by fish. The adjacent surface water and sediment quality is likely due to upstream sources and not site releases. Areas where significant ecological resources exist are not likely to be adversely impacted by planned future site uses. The ecological assessment did not identify the need for any remediation.

2.6 HUMAN HEALTH RISKS

2.6.1 Introduction

A Baseline Risk Assessment was prepared to analyze the potential adverse human health effects (current and future) resulting from exposures to site-related chemicals found at Cameron Station. The full risk assessment was presented as Chapter 6 of the document entitled Cameron Station Remedial Investigation Draft Report, August, 1992. The procedures used in this risk assessment were consistent with USEPA guidance, the Risk Assessment Guidance for Superfund, Volume - Human Health Evaluation Manual (RAGS) (USEPA 1989a) and supplemental guidance (USEPA 1991b), the Guidance for Data Useability in Risk Assessment (Part A) (USEPA 1990), the Exposure Factors Handbook (USEPA 1989b), and the Superfund Exposure Assessment Manual (USEPA 1988b).

The location, description, and history of the Cameron Station site are presented in Section 2.1. Features of the site pertinent to the risk assessment are shown in Figure 2-2. Characteristics of the physical setting of the site relevant to potentially exposed populations are presented in the Exposure Assessment section below.

Activities performed in support of the Cameron Station RI included a site reconaissance, geophysical surveys, soil gas surveys, UST integrity testing, an asbestos survey of buildings, an assessment of PCB transformers, studies of sanitary and storm sewers, a survey of biological contamination from pigeon roosting, and sampling and analysis of environmental media.

2.6.2 Chemicals of Potential Concern

Surface and subsurface soil, groundwater, surface water, sediment, and fish tissue were the media of concern at Cameron Station.

The following conservative process was applied to select the eighty-one chemicals of potential concern presented in Table 2-1:

- As a general rule, any chemical detected at least once in any sampled medium where human exposures or releases to the environment may occur was considered a candidate chemical of potential concern.

- Comparison of sample concentrations with background concentrations was not used to select chemicals of potential concern. However, beneficial minerals (iron, calcium, zinc, etc.) were excluded if the estimated intake from site media did not exceed the National Research Council's health criterion. Also, essential nutrients that had available inhalation reference doses or slope factors (hexavalent chromium) were retained as chemicals of potential concern. Any unacceptable risks they may contribute were evaluated as an uncertainty in the risk assessment.

- Laboratory artifacts or chemicals determined to be blank contaminants unrelated to known site activities were not selected as chemicals of potential concern if the rules outlined above were satisfied.

Exposure point concentrations of the chemicals of potential concern on which the risk assessment was based are presented by environmental medium and exposure point in Appendix B.

2.6.3 Exposure Assessment

Exposure scenarios used for estimation of human risk at Cameron Station are presented in Table 2-2.

For purposes of the exposure assessment, the Cameron Station site was defined as the area within Cameron Station property boundaries, the segments of Holmes and Backlick Runs adjacent to the property, and Cameron Run down to the most distant location where samples were collected for the RI.

A landfill is present on the southern side of the site and is considered a part of the site. Currently, it is mostly unvegetated and represents a potential source of exposure to airborne soil particles at the landfill or at locations downwind of the landfill due to wind erosion. Another potential source of airborne soil particles is an unpaved road located along the west and southwest boundaries of the site used by service vehicles and cars driven by site visitors. The surface of this service road may contain residue from fly ash or road oil of unknown chemical concentration or origin.

An area around Building 23 (PX service station) where TPHC contamination is present in subsurface soil is likely to be a source of airborne releases of VOCs commonly associated with TPHC.

On-site areas where visitors are most likely to come in contact with potentially contaminated environmental media by one or more exposure routes include the following:

- Cameron Lake
- Streams
- Ball field
- Picnic grounds
- Jogging trail

The commissary, the administration building, and the various offices on the site are areas that are accessible to visitors but are not areas where exposures to contaminants are probable. The site history of these areas suggests that they have not been impacted by previous chemical releases. These areas are also upwind from major site sources.

Several site areas were found to be impacted by site chemicals but, due to their remote location or limited accessibility, were not judged to be significant areas where human exposure could potentially occur under the current and future land use scenarios. These included covered acid pits, septic tanks and ash piles.

The on-site lake (Cameron Lake) and streams near the site (Backlick Run, Holmes Run and Cameron Run) are areas where children may wade and play. Surface water and sediments in these areas may contain chemicals released from the site.

Activities by maintenance workers could lead to direct exposures to chemicals in the identified areas. Areas of potentially contaminated soil near Building 30 and along fencelines are potential exposure points for these maintenance workers.

Future use of the site is planned to alter the current physical setting of the northern area of the site. Land use in areas where buildings are presently located is planned to switch from commercial/light industrial to residential. Contaminated soils in some of these areas where exposures do not occur now may become yards and recreational areas where human exposure to contaminants in soil can occur in the future. The potential for VOC releases to the air from subsurface soil and groundwater contamination could increase as a result of removal of overlying pavement and buildings.

Several areas associated with the site are not planned to change under site reuse. On-site recreational areas are planned to remain unaltered due to their present location in the flood plain of surrounding streams and the high land use priority placed on recreational use of those areas. No specific plans are available for a different use of the landfill area. However, it is unlikely that the landfill will be used as a site for construction of residential homes or commercial buildings because of its location near the railroad tracks. Due to natural site topography and the lack of alternative channels for transporting runoff, it is also likely that the current status of streams adjacent to the site will not change.

Chemical emission and air dispersion modeling were performed for specific areas where there were known sources of contaminants and where releases of contaminated soil particles or volatile organic compounds to air from contaminated soils and groundwater were likely to occur. Particulate emissions were considered likely to occur from bare, unvegetated, erodible, contaminated surface soils and VOC emissions were considered likely to occur from areas that are not covered by buildings, concrete, or asphalt where surface and subsurface soils or groundwater were contaminated with VOCs. The first type of area occurred at the landfill, the service road, and soil near Building 30. The second type of area included the area near Building 23 where subsurface TPHC contamination exists and the two areas where groundwater is contaminated with trichloroethylene, benzene, and other VOCs under a planned future housing area.

Only very small soil particles are inhaled and retained in the lungs and are a concern as a health risk (USEPA 1989a). These are referred to as "PM10" particles or particles with an aerodynamic diameter of 10 microns or less. Releases and ambient outdoor air concentrations of contaminated PM10 particles from bare, unvegetated, erodible, contaminated surface soils were estimated for wind erosion and vehicle traffic disturbances using the method of Cowherd et al. (1985) and a simple box (Hanna et al. 1982) or Gaussian plume model (Turner 1970, USEPA 1988b).

Emissions of VOCs to air from TPHC-contaminated soil were conservatively estimated using the Shen soil volatilization model (Shen 1981). Emissions of benzene and trichloroethylene to air from groundwater were estimated using a model developed by USEPA for Resource Conservation and Recovery Act (RCRA) facility investigations (USEPA 1989c). A simple box (Hanna et al. 1982) or Gaussian plume model (Turner 1970) was used to conservatively estimate exposure point concentrations for VOCs using model emission estimates and local wind speed.

Exposure time, frequency, and duration terms used in the Cameron Station exposure assessment are presented in Tables 2-3 (inhalation terms) and 2-4 (ingestion and dermal contact terms).

2.6.4 Toxicity Assessment

Oral and inhalation cancer slope factors (CSFs) have been developed by EPA's Carcinogen Risk Assessment Verification Endeavor (CRAVE) Work Group for estimating excess lifetime cancer risks associated with exposure to potentially carcinogenic chemicals. CSFs, which are expressed

in units of $(mg/kg\text{-}day)^{-1}$, are multiplied by the estimated intake of a potential carcinogen in mg/kg-day to provide an upper-bound estimate of the excess lifetime cancer risk associated with exposure at that intake level. The term "upper bound" reflects the conservative estimate of the risks calculated from the CSF. Use of this approach makes underestimation of the actual cancer risk highly unlikely. CSFs are derived from the results of human epidemiological studies or chronic animal bioassays to which animal-to-human extrapolation and other uncertainty factors have been applied.

In addition, EPA assigns a cancer weight-of-evidence category to each chemical in order to reflect the overall confidence that the chemical is likely to cause cancer in humans. These categories and their meanings are summarized below.

Category	Meaning	Basis
A	Known human carcinogen	Sufficient evidence of increased cancer incidence in exposed humans.
B1	Probable human carcinogen	Limited human data are available.
B2	Probable human carcinogen	Sufficient evidence of increased cancer incidence in animals, but lack of data or insufficient data from humans.
C	Possible human carcinogen	Suggestive evidence of carcinogenicity in animals.
D	Cannot be evaluated	No evidence or inadequate evidence of cancer in animals or humans.

Oral reference doses (RfDs) and inhalation reference concentrations (RfCs) have been developed by EPA's RfD/RfC Work Group for indicating the potential for adverse health effects from exposure to chemicals exhibiting noncarcinogenic effects. RfDs, which are expressed in units of mg/kg-day, and RfCs, which are expressed in units of mg/m^3, are estimates of exposure

levels for humans, including sensitive individuals, that are likely to be without an appreciable risk of noncarcinogenic, deleterious effects during a lifetime. Estimated levels of exposure to a chemical in environmental media (e.g., the amount of a chemical ingested from contaminated drinking water) can be compared to the RfD or RfC. RfDs/RfCs are derived from human epidemiological studies or animal studies to which uncertainty factors have been applied (e.g., to account for the use of animal data to predict effects on humans). These uncertainty factors help ensure that the RfDs/RfCs will not underestimate the potential for adverse noncarcinogenic effects to occur.

Table 2-5 summarizes the carcinogenic effects and slope factors and Table 2-6 summarizes the noncarcinogenic effects and critical toxicity values for contaminants of potential concern at Cameron Station.

2.6.5 Risk Characterization

Appendix C presents carcinogenic and noncarcinogenic risks by chemical for each exposure medium and pathway and summarizes total pathway risk.

Noncarcinogenic Effects

Potential concern for noncarcinogenic effects of a single contaminant in a single medium is expressed as the hazard quotient (HQ), which is the ratio of the estimated level of exposure derived from the contaminant concentration in a given medium to the contaminant's RfD or RfC. By adding the HQs for all contaminants within a given medium or across all media to which a given population may reasonably be exposed, the Hazard Index (HI) can be generated. The HI provides a useful reference point for gauging the potential significance of multiple contaminant exposures within a single medium or across media.

No HIs exceeded 1.0 for any population at the Cameron Station site. Therefore, no noncancer health effects are expected from exposure to potentially site-related chemicals.

Carcinogenic Risks

Excess lifetime cancer risks are determined by multiplying the intake level by the cancer slope factor. These risks are probabilities that are generally expressed in scientific notation (for example, 1 x 10^{-6} or 1E-6). An excess lifetime cancer risk of 1 x 10^{-6} indicates that, as a plausible upper bound, an individual has a one in one million chance of developing cancer as a result of site-related exposure to a carcinogen over a 70-year lifetime under the specific exposure conditions at a site.

Table 2-7 presents estimated total cancer risks for each population exposed at a sub-location of Cameron Station where at least one pathway-specific risk is likely to be 1E-6 or greater.

Under current land use conditions, only two populations are subject to potential increased cancer risk due to exposure to contaminated environmental media at Cameron Station. Maintenance workers exposed to fenceline soils may be subject to an increased excess cancer risk of 2E-6 as a result of dermal exposure to dioxin-contaminated soils in this area. Children may be exposed to an increased excess cancer risk of 4E-5 from ingesting fish caught in Cameron Lake that contained PCB-1260 and dioxins. This risk is likely to be significantly overestimated due to values assumed for exposure calculations and estimation of cancer risks for less than lifetime exposures. Sediment-bound PCB-1260 and dioxins in Cameron Lake are likely to be the source of these chemicals in fish tissue. However, these chemicals were not detected in Cameron Lake sediment. Based on model estimates of air concentrations, subsurface contamination by trichloroethylene and VOCs associated with TPHCs does not present excess risks to exposed individuals that exceed 1E-12.

Future child residents may experience elevated excess cancer risks (7E-5) from eating fish from Cameron Lake and ingesting and contacting yard and landfill soils. Future adult residents may experience elevated cancer risks (3E-5) from ingestion and dermal contact with contaminated yard soil. These risks are due to the presence of PCB-1260 in fish (for children), and beryllium, dieldrin, dioxins, heptachlor, and PCB-1260 in soil where future yards may be located. Based on model estimates of air concentrations, subsurface concentrations of benzene, trichloroethylene, and VOCs associated with TPHCs do not present excess risks to exposed

individuals that exceed 1E-12.

2.6.6 Uncertainties in the Baseline Risk Assessment

An analysis of significant sources of uncertainty in the baseline risk assessment indicates that total site risks may be overestimated due primarily to: (1) The use of conservative values for exposure factors; (2) Calculation of risks for infrequently detected chemicals; and (3) Calculation of risk for chemicals (i.e., beryllium) present at site locations at concentrations not statistically different from ambient levels.

2.7 ENVIRONMENTAL RISKS

2.7.1 Ecological Risk Under Current Land Use Conditions

No significant ecological resources exist in the terrestrial environment at the Cameron Station site as a result of its developed nature. Significant aquatic resources exist in Cameron Lake and surface streams on the south and east borders of the site. No critical habitats nor endangered species were identified at the site. No adverse effects, therefore, would result to critical habitats or endangered species from site conditions.

A productive fishery exists in Cameron Lake. Cameron Lake is also used by migratory waterfowl. Transient individuals of native species of wildlife may use streams near the site, although none were observed during site reconnaissance.

Seven metals (aluminum, barium, beryllium, chromium, copper, iron, and zinc) and three organic compounds (fluoranthene, phenanthrene and pyrene) are elevated in Cameron Lake sediments by a factor of 10 over concentrations observed in sediment at background stream reference locations. Evidence of effects levels at other sites indicates that concentrations of copper, lead and zinc at or below levels observed in Cameron Lake sediments may cause adverse effects in biota, primarily benthic organisms, exposed to contaminated sediments.

Ambient water concentrations of aluminum, cadmium, silver and zinc in nearby streams exceed ambient water quality criteria for protection of aquatic life and toxic levels in bioassays. These are more likely due to releases from upstream sources than from Cameron Station. Cadmium,

lead, silver, and zinc concentrations in Cameron Lake also exceeded AWQCs, but their concentrations were typical of those found in urban runoff.

2.7.2 Ecological Risk Under Future Land Use Conditions

Areas where significant ecological resources exist near this site are unlikely to be impacted adversely by planned reuse. Waterfowl, urban wildlife and transient native species are likely to relocate to other nearby areas in response to any changes affecting aquatic resources at the site.

2.8 DESCRIPTION OF ALTERNATIVES

Selection of the remedial action alternatives was conducted through a systematic screening process described in detail in the FS report. The alternatives were developed from technology types and process options that can be effectively implemented at the site. Once the alternatives were developed, they were evaluated for effectiveness, implementability and cost. The remedial alternatives discussed in this section represent alternatives retained after this screening process. The Army's preferred alternative for remediating each OU is indicated. Preferred alternatives were selected based on a comparative analysis of all alternatives described later in this document.

2.8.1 OU-1 PCB Transformer Service, Storage and Spill Areas

Alternative 1-1:	No Action.
Alternative 1-2:	Excavation and Off-Site Disposal in RCRA Landfill. (Preferred)
Alternative 1-3:	Excavation and Off-Site Thermal Oxidation.

Alternative 1-1: No Action

Estimated Capital Cost: $0
Estimated Annual O&M Cost: $0
Estimated Present Worth: $0
Estimated Duration: None

The Superfund program requires that the "no action" alternative be evaluated at every site to establish a baseline for comparison. The no action alternative will involve no remedial action. The site will remain in its current condition. Although significant PCB contamination does not exist, remediation is being proposed since the site will be made available for unrestricted use.

Alternative 1-2: Excavation and Off-Site Disposal in RCRA Landfill (Preferred)

Estimated Capital Cost: $16,300
Estimated Annual O&M Cost: $0
Estimated Present Worth: $16,300
Estimated Duration: one month

Approximately 10 cubic yards (CY) of PCB and pesticide-containing material in OU-1 will be excavated and removed to an off-site, RCRA Subtitle C landfill. The excavated area will be backfilled with clean soil and covered with asphalt. Placement of the wastes in an off-site permitted landfill will reduce the mobility of PCBs and pesticides.

Alternative 1-3: Excavation and Off-Site Thermal Oxidation

Treatment Components:

Estimated Capital Cost: $38,100
Estimated Annual O&M Cost: $0
Estimated Present Worth: $38,100
Estimated Duration: one month

This alternative is similar to Alternative 1-2 except that the excavated materials will be treated by an off-site RCRA permitted thermal treatment facility. The off-site thermal treatment facility will comply with emission standards for incinerators. The resulting ash will be disposed of by the thermal treatment facility. Thermal treatment of the contaminated wastes provides multiple benefits of reducing the toxicity and volume of PCBs and pesticides.

2.8.2 OU-3 Landfill

Alternative 3-1: No Action.
Alternative 3-2: Soil Capping, and Monitoring the Landfill. (Preferred)

Alternative 3-1: No Action

Estimated Capital Cost: $0
Estimated Annual O&M Cost: $0
Estimated Present Worth: $0
Estimated Duration: None

The Superfund program requires that the "no action" alternative be evaluated at every site to establish a baseline for comparison. The no action alternative will involve no remedial action. The site will remain in its current condition. Results of the baseline risk assessment indicated that no excess cancer risk was associated with the landfill area. Although widespread contamination was not identified, remedial action consisting of capping the landfill is being proposed to minimize the potential for future impacts to groundwater.

Alternative 3-2: Soil Capping, and Monitoring the Landfill (Preferred)

Estimated Capital Cost: $36,900
Estimated Annual O&M Cost: $7,700
Estimated Present Worth: $96,400
Estimated Duration: Approximately one year

The total area of the soil cap will be approximately 20,000 square feet. The conceptual design of the cap includes from bottom to top: an 18-inch-thick layer of compacted native soil, a 6-inch-thick layer of topsoil, and a vegetation cover. The cap will be designed to meet the state requirements for the closure of unpermitted construction/demolition/debris landfills. The soil cap will reduce leachate generation and thus protect groundwater.

2.8.3 OU-4 Pesticides Use and Storage Area

Alternative 4-1: No Action.
Alternative 4-2: Excavation and Off-Site Disposal in RCRA Landfill. (Preferred)
Alternative 4-3: Excavation and Off-Site Thermal Oxidation.

Alternative 4-1: No Action

Estimated Capital Cost: $0
Estimated Annual O&M Cost: $0
Estimated Present Worth: $0
Estimated Duration: None

The Superfund program requires that the "no action" alternative be evaluated at every site to establish a baseline for comparison. The no action alternative will involve no remedial action. The site will remain in its current condition.

Alternative 4-2: Excavation and Off-Site Disposal in RCRA Landfill (Preferred)

Estimated Capital Cost: $27,000
Estimated Annual O&M Cost: $0
Estimated Present Worth: $27,000
Estimated Duration: one month

Approximately 20 cubic yards (CY) of pesticides containing wastes in and around the Building 30 septic tank and the septic tank itself will be excavated and removed to an off-site, RCRA Subtitle C landfill. The excavated area will be backfilled with clean soil. Placement of the wastes in an off-site permitted landfill will reduce the mobility of pesticides.

Alternative 4-3: Excavation and Off-Site Thermal Oxidation

Estimated Capital Cost: $72,000
Estimated Annual O&M Cost: $0
Estimated Present Worth: $72,000
Estimated Duration: one month

This alternative is basically the same as Alternative 4-2 except that the excavated materials will be treated by an off-site RCRA permitted thermal treatment facility. The off-site thermal treatment facility will comply with emission standards for incinerators. The resulting ash will be disposed of by the thermal treatment facility. Thermal treatment of the contaminated wastes provides multiple benefits of reducing the toxicity and volume of pesticides.

2.8.4 OU-5 Sanitary and Storm Sewer Systems

Alternative 5-1:	No Action.
Alternative 5-2:	Groundwater Collection Followed by Air Stripping and Discharge to Surface Water (Preferred)
Alternative 5-3:	Groundwater Collection Followed by Liquid Phase Carbon Adsorption and Discharge to Surface Water

Alternative 5-1: No Action

Estimated Capital Cost: $0
Estimated Annual O&M Cost: $7,700
Estimated Present Worth: $118,400
Estimated Duration: None

The Superfund program requires that the "no action" alternative be evaluated at every site to establish a baseline for comparison. The no action alternative will involve no remedial action other than annual VOC analyses of groundwater samples collected from existing monitoring wells. There will be no reduction in toxicity, mobility or volume of contaminants except through natural fate and transport processes.

Alternative 5-2: **Groundwater Collection Followed by Air Stripping and Discharge to Surface Water** (Preferred)

Estimated Capital Cost: $213,000
Estimated Annual O&M Cost: $53,400
Estimated Present Worth: $1,034,200
Estimated Duration: Thirty years

Trichloroethene (TCE) contaminated groundwater in OU-5 will be pumped at a flow rate of approximately 40 gallons per minute (gpm) and remediated with an air stripping unit to remove VOCs. The need for pretreatment for removal of certain metals will be evaluated in pilot studies and if needed, would be implemented. The treated groundwater will be discharged to Backlick Run via an underground pipe. It is estimated that the volatile organic emission rate from the air stripper would be approximately 0.3 lb/day. The air discharged from the stripper will be routed through a granular activated carbon filter for removal of the VOCs. No VOCs, therefore, will be discharged to the atmosphere at the site. Reduction in groundwater contamination is provided by this alternative. Since this remedial action would be ongoing at the time of property transfer, transfer documents will reflect the remediation of OU-5. The Army has selected Alternative 5-2 with carbon treatment of the air discharge stream after considering the Alexandria Health Department's comments concerning the on-site discharge of VOCs associated with Alternative 5-2 without such treatment. Alternative 5-2 (without treatment of the air discharge) had been identified as the preferred alternative in the Proposed Plan. The estimated rate of VOC emissions to the atmosphere at the site from the air stripper had been judged not to represent a significant environmental or human health concern. In response to the Health Department's request, however, carbon treatment of the air discharge has been added to the remedial alternative.

The level of protectiveness from the revised Alternative 5-2 will be the same as that from Alternative 5-3 (no on-site emissions) while providing a significant cost savings. In fact, it is estimated that the present worth of Alternative 5-2 with carbon treatment of the air discharge may be less than the estimated present net worth of Alternative 5-2 without the carbon treatment of the air discharge due to reductions in the overall O&M costs over the life of the project.

Alternative 5-3: **Groundwater Collection Followed by Liquid Phase Carbon Adsorption and Discharge to Surface Water**

Estimated Capital Cost: $234,900
Estimated Annual O&M Cost: $56,100
Estimated Present Worth: $1,097,300
Estimated Duration: Thirty years

This alternative is similar to Alternative 5-2 except that the extracted groundwater will be treated by a liquid phase carbon adsorption unit (two canisters in series). The carbon consumption rate is estimated to be approximately 3 lbs/day, which will not pose unacceptable health risks to the public. The spent activated carbon will be shipped to the carbon supplier for off-site regeneration. Reduction in groundwater contamination is also provided by this alternative.

2.8.5 OU-6 Acid Pits

Alternative 6-1: No Action.
Alternative 6-4: Excavation and Off-Site Thermal Oxidation and Solidification. (Preferred)

Alternative 6-1: **No Action**

Estimated Capital Cost: $0
Estimated Annual O&M Cost: $0
Estimated Present Worth: $0
Estimated Duration: None

The Superfund program requires that the "no action" alternative be evaluated at every site to establish a baseline for comparison. The no action alternative will involve no remedial action. The site will remain in its current condition.

Alternative 6-4: **Excavation and Off-Site Thermal Oxidation and Solidification (Preferred)**

Estimated Capital Cost: $44,600
Estimated Annual O&M Cost: $0
Estimated Present Worth: $44,600
Estimated Duration: one month

Approximately ten cubic yards (CY) of TPHC and metal contaminated soils will be excavated from two acid pit areas for disposal in a RCRA permitted thermal treatment facility. The excavated area will be backfilled with clean soil. The off-site thermal treatment facility will comply with technical standards for incinerators. Thermal treatment of the contaminated wastes reduces the toxicity and volume of organic compounds. Metals in the ash will be solidified before disposal. Thermal treatment of the contaminated wastes reduces the toxicity and volume of organics. Solidification is also widely used to immobilize metal contents in the waste.

2.8.6 OU-8 PX Service Station and Building 2 Underground Storage Tanks

Alternative 8-1:	No Action.
Alternative 8-2:	Groundwater Collection Followed by Air Stripping System and Discharge to Surface Water.
Alternative 8-3:	Groundwater Collection Followed by Liquid Phase Carbon Adsorption and Discharge to Surface Water.
Alternative 8-4:	Groundwater Collection Followed by Air Stripping and In-Situ Bioremediation. (Preferred)

Alternative 8-1: **No Action**

Estimated Capital Cost: $0
Estimated Annual O&M Cost: $7,700
Estimated Present Worth: $118,400
Estimated Duration: None

The Superfund program requires that the "no action" alternative be evaluated at every site to establish a baseline for comparison. The no action alternative will involve no remedial action other than annual VOC analyses of groundwater samples collected from existing monitoring wells. There will be no reduction in toxicity, mobility or volume of contaminants except through natural fate and transport process.

Alternative 8-2: Groundwater Collection Followed by Air Stripping and Discharge to Surface Water

Estimated Capital Cost: $148,200
Estimated Annual O&M Cost: $53,400
Estimated Present Worth: $750,200
Estimated Duration: Approximately seventeen years

Petroleum contaminated groundwater (BTEX) in OU-8 will be pumped at a rate of approximately 40 gallons per minute (gpm) and remediated with an air stripping unit to remove volatile organics. The treated groundwater will be discharged to Backlick Run via an underground pipe. It is estimated that the volatile organic emission rate from the air stripping system will be approximately 12 lbs/day which will not pose unacceptable health risks to the public. Reduction in groundwater contamination is provided by this alternative.

Alternative 8-3: Groundwater Collection Followed by Liquid Phase Carbon Adsorption and Discharge to Surface Water

Estimated Capital Cost: $184,500
Estimated Annual O&M Cost: $171,300
Estimated Present Worth: $2,115,800
Estimated Duration: Approximately seventeen years

This alternative is similar to Alternative 8-2 except that the extracted groundwater will be treated by a liquid phase carbon adsorption unit (two canisters in series). The carbon consumption rate is estimated to be approximately 120 lbs/day (assuming 10 % adsorption capacity). The spent activated carbon will be shipped to the carbon supplier for off-site regeneration. Reduction in groundwater contamination is also provided by this alternative.

Alternative 8-4: **Groundwater Collection Followed by Air Stripping and In-Situ Bioremediation** (Preferred)

Estimated Capital Cost: $293,700
Estimated Annual O&M Cost: $83,100
Estimated Present Worth: $935,400
Estimated Duration: Approximately ten years

BTEX contaminated groundwater will be extracted from downgradient of the aquifer at a flow rate of approximately 40 gpm. The extracted groundwater will be stripped to remove dissolved VOCs. Oxygen (delivered as a dilute solution of hydrogen peroxide) and nutrients (such as nitrogen and phosphorus),if needed, will be introduced to the treated effluent using a surface mixing tank. The oxygen-enriched groundwater will then be reinjected upgradient of the contaminated aquifer. When the oxygen-enriched injected water flows through the contaminated aquifer, the presence of the dissolved oxygen and nutrients should stimulate biodegradational activities of microorganisms in the aquifer thus enhancing the naturally occurring biological reactions. The organic contaminants (such as BTEX) in the groundwater will be destroyed by the stimulated biological reaction. This alternative will effectively reduce the toxicity and volume of the contaminants in the groundwater. Since this remedial actin will be ongoing at the time of property transfer, transfer documents will reflect remediation of OU-8.

2.9 SUMMARY OF THE COMPARATIVE ANALYSIS OF ALTERNATIVES

Selection of preferred alternatives for each OU were made after performing a detailed analysis for all alternatives described above. Each alternative was evaluated against the nine criteria established by EPA under CERCLA to evaluate potential remedial process alternatives. The nine evaluation criteria are:

- Overall protection of human health and the environment;
- Compliance with ARARs;
- Long-term effectiveness;
- Reduction of toxicity, mobility or volume;
- Short-term effectiveness;
- Implementability;
- Cost;

- State acceptance; and
- Community acceptance.

Two criteria, overall protection of human health and the environment; and compliance with ARARs, are threshold factors. Two criteria, state acceptance and community acceptance, are modifying considerations. The remaining criteria are the primary balancing factors. A brief description of each criteria is provided in Appendix D.

For each operable unit, based upon current information, the preferred alternative appears to provide the best balance with respect to the nine criteria. This section profiles the performance of the preferred alternatives against these nine criteria. Results of the evaluation are further summarized in Tables 2-8 through 2-13.

2.9.1 Overall Protection of Human Health and the Environment

The no-action alternative does not protect human health or the environment from potential risks posed by the contaminated materials, and thus it is not considered further in this analysis as an option for any OU on the site. Alternatives 1-2, 1-3, 4-2, 4-3, and 6-4 will achieve the soil remediation objective of preventing worker exposure to contaminated soils and protecting the human health and the environment by reducing the potential risk from direct contact with contaminants. The soil cap applied in Alternative 3-2 will reduce direct contact with the landfilled materials, minimize surface water infiltration and thus promote groundwater protection, and meet the landfill closure requirements.

Alternatives 5-2, 5-3, 8-2, 8-3 and 8-4 will achieve the remedial objectives for groundwater. The preferred alternative 5-2 is more cost-effective than alternative 5-3. The preferred alternative 8-4 provides the fastest time for groundwater restoration.

The no-action alternative provides no remedial measures, no risk reductions, and does not achieve remedial action objectives and is not evaluated further.

2.9.2 Compliance with Applicable or Relevant and Appropriate Requirements (ARARs)

It is expected that Alternatives 1-2, 1-3, 3-2, 4-2, 4-3, and 6-4 will meet action-specific ARARs. The Federal Safe Drinking Water Act (SDWA) provides for protection of human health from contaminants in drinking water by establishing MCLs. These requirements will be met under Alternatives 5-2, 5-3, 8-2, 8-3 and 8-4. A list of state and Federal ARARs attained by the preferred alternatives for each operable unit are included in Tables 2-14 through 2-16.

2.9.3 Long-Term Effectiveness and Permanence

Under Alternatives 1-2, 1-3, 4-2, 4-3, and 6-4, the contaminated materials will be excavated and transported off-site for landfill or incineration. Therefore risk through direct exposure to the contaminated waste will be eliminated by meeting clean-up goals with these alternatives. Incineration provides the highest level of long-term effectiveness because contaminants will be destroyed or reduced in volume during incineration. The soil cap applied under Alternative 3-2 will minimize the direct exposure to the landfilled materials. Moreover, the soil cap and revegetation are likely to be effective in reducing the amount of infiltration and surface runoff.

Alternatives 5-2, 5-3, 8-2, 8-3 and 8-4 will provide for permanent removal of VOCs from the groundwater through the treatment processes. Under optimum operational conditions, Alternative 8-4 will offer the greatest long-term effectiveness because of quicker aquifer restoration by in-situ microbial reactions.

2.9.4 Reduction in Toxicity, Mobility and Volume of the Contaminants Through Treatment

Alternatives 1-2 and 4-2 will reduce the mobility of the contaminants through placement in an off-site RCRA landfill. Alternatives 1-3 and 4-3 provides the multiple benefits of reducing toxicity and volume of the PCBs and pesticides through thermal treatment (incineration). Alternative 6-4 will also reduce the toxicity and volume of petroleum contaminated soils. The ash generated by the incinerator will be solidified to immobilize the metal contents. Alternative 3-2 will reduce the mobility of the contaminants by reducing the potential for leaching.

The air stripping system applied in Alternatives 5-2 and 8-2 will effectively remove VOCs in groundwater, but will not reduce the toxicity, mobility or volume of contaminants. However, volume and mobility reduction will be achieved by carbon adsorption in Alternatives 5-3 and 8-3. Toxicity will be reduced if the spent carbon is thermally regenerated. Alternative 8-4 will effectively reduce the toxicity and volume of contaminants in groundwater through in-situ biological reactions.

2.9.5 Short-Term Effectiveness

There will be no risks to the public or environment during the implementation of the no-action alternatives because no remedial actions will occur. The short-term risks to the community and environment associated with Alternatives 1-2, 1-3, 3-2, 4-2, 4-3, and 6-4 will be minimal, because construction is expected to occur over a short period of time (from 1 month to 1 year) and risks could be mitigated through the use of dust control. Workers may be exposed to contaminants during implementation of these alternatives, but the risks will be minimized through the use of appropriate personal protection equipment.

Alternatives 5-2, 5-3, 8-2 and 8-3 involve the installation of extraction wells and construction of a groundwater treatment system on-site. Alternative 8-4 will have similar short-term effects as the above alternatives, but more extensive construction activities are required to implement this alternative (i.e., the injection system and a more extensive piping system will be installed). VOC emissions from the air stripping system in Alternatives 5-2 and 8-2 will not pose unacceptable risk to the community and the environment due to its relatively low emission rate. It is expected that treated water from Alternatives 5-2, 5-3, 8-2 and 8-3 will meet surface water standards and will be discharged to Backlick Run. It is estimated that the time required to reach the groundwater cleanup goals is approximately 30 years for Alternatives 5-2 and 5-3, approximately 17 years for Alternatives 8-2 and 8-3, and approximately 10 years for Alternative 8-4. Workers may be exposed to contamination during implementation of these alternatives, but the risks will be minimized through the use of appropriate personal protection equipment.

2.9.6 Implementability

Alternatives 1-2, 1-3, 4-2, 4-3 and 6-4 are proven and reliable for achieving the specified cleanup goals for soil contamination. Soil capping in Alternative 3-2 is also easy to implement. All other equipment, materials, and services for performance of these alternatives are readily available.

Alternatives 5-2, 5-3, 8-2 and 8-3 are relatively easy to implement. The proposed treatment technologies in Alternatives 5-2, 5-3, 8-2 and 8-3 are proven and reliable for removal of VOCs from contaminated groundwater. The equipment and materials needed for implementation of these alternatives are readily available. Alternative 8-4 will be slightly less implementable from a technical standpoint than other alternatives, because of the unpredictable in-situ microbial reactions. Alternative 8-4 will also be less implementable from an administrative standpoint than other alternatives, due to permits required for injection of oxygen- and nutrients-enriched groundwater. The effectiveness of these alternatives will be evaluated by sampling and analysis of groundwater and treated water. Treatability studies are recommended to verify and optimize the effectiveness of treatment processes in Alternatives 5-3, 8-3 and 8-4.

2.9.7 Costs

The present worth costs of the preferred alternatives are listed below:

Alternative 1-2	$16,300
Alternative 3-2	$96,400
Alternative 4-2	$27,000
Alternative 5-2	$1,034,200
Alternative 6-4	$44,600
Alternative 8-4	$935,400

The estimated present worth costs for the other remaining alternatives are as follow:

Alternative 1-3	$38,100
Alternative 4-3	$72,000
Alternative 5-1	$118,400
Alternative 5-3	$1,097,300

Alternative 8-1	$118,400
Alternative 8-2	$750,200
Alternative 8-3	$2,115,800

The preferred alternatives have been judged to be cost effective means of achieving the necessary level of compliance with health protection and other regulatory requirements.

2.9.8 State Acceptance

The Commonwealth of Virginia has concurred with the preferred remedial alternatives outlined in this document.

2.9.9 Community Acceptance

Community acceptance is assessed in the attached Responsiveness Summary. The Responsiveness Summary provides a review of the public comments received on the Proposed Plan. Based on the limited number of public comments received, and modifications made to address these comments, community acceptance of the preferred remedial alternatives has been assumed.

2.10 THE SELECTED REMEDY

After careful consideration of the proposed alternatives, the Army's preferred alternative for each of the six OUs are listed below with estimated risks calculated during the FS (Life Systems, Inc., 1992). A description of these preferred alternatives is provided in Section 2.8 of this document. Any potential future cleanup that may be required for the benzene and 1,2-DCA contamination observed in OU-5 will be addressed in a separate ROD.

- OU-1, Alternative 1-2 — Excavation of approximately 10 cubic yards of PCB and pesticide-containing material and disposal at an off-site RCRA Subtitle C landfill. The noncancer hazard index and cancer risk estimate associated with this alternative could not be recalculated due to unavailable slope factors.

- OU-3, Alternative 3-2 — Soil capping and monitoring of the approximately 20,000 square foot landfill. The cap will be designed to meet the state requirements for the closure of unpermitted construction/demolition/ debris landfills. The noncancer hazard index associated with this alternative was calculated at 2.7E-2; the cancer risk was estimated at 1.6E-7.

- OU-4, Alternative 4-2 — Excavation of approximately 20 cubic yards of pesticide-containing wastes around the Building 30 septic tank, removal of the septic tank, and disposal at a RCRA Subtitle C landfill. The noncancer hazard index associated with this alternative was calculated at 2.2E-8; the cancer risk was estimated at 2.6E-11.

- OU-5, Alternative 5-2 — Groundwater Collection followed by Air stripping and discharge to Surface Water (with carbon treatment of air discharge) of TCE and 1,1-DCE contaminated groundwater near Building 2. The noncancer hazard index associated with this alternative was calculated at 2.2E-06 to 1.2E-08; the cancer risk was estimated at 3.6E-7 to 7.4E-10.

- OU-6, Alternative 6-4 — Excavation of approximately 10 cubic yards of TPHC and metal contaminated soils from two acid pit locations for disposal in an off-site RCRA permitted thermal treatment facility. Metals in the ash will be solidified before disposal. The noncancer hazard index associated with this alternative was calculated at 2.6E-03; the cancer risk was estimated at 1.6E-8.

- OU-8, Alternative 8-4 — Groundwater Collection followed by Air Stripping and In-Situ Bioremediation of BTEX contaminated groundwater near the Building 2 and the PX Service Station. The noncancer hazard index associated with this alternative was calculated at 9.6E-4 to 1.7E-5; the cancer risk was estimated at 8.5E-7 to 1.7E-9.

Tables 2-17 and 2-18 describe the cleanup goals that were determined in the FS to be appropriate for the various chemicals of concern and media type. However, the Virginia DEQ will make the final determination of the acceptable level of cleanup. For instance, OU-8 is being handled under the supervision of DEQ's Water Division per Virginia Regulation VR 680-13-02, Sections 6.3, 6.4, 6.5 and 6.6. Any potential future cleanup that may be required for the benzene and 1,2-DCA contamination observed in OU-5 will be addressed in a separate ROD.

2.11 STATUTORY DETERMINATIONS

Section 121 of CERCLA has established several statutory requirements and preferences for remedial actions. Under this section the selected remedy must:

- Be protective of human health and the environment;
- Comply with ARARs (or justify an ARAR waiver);
- Be cost-effective;
- Utilize permanent solutions and alternative treatment technologies or resource recovery technologies to the maximum extent practicable; and
- Satisfy the preference for treatment that reduces toxicity, mobility, or volume as a principal element, or provide an explanation as to why this preference is not satisfied.

This section provides a brief discussion of how the selected remedy meets the statutory requirements and preferences of CERCLA Section 121 described above.

2.11.1 Protection of Human Health and the Environment

The selected remedy would protect the human health and the environment by reducing the potential risk from direct contact with contaminated soils. Capping of the landfill will reduce direct contact with the landfilled materials and promote groundwater protection by minimizing surface water infiltration. Remediation of the groundwater will reduce the discharge of contaminated groundwater to surface water pathways and lower contaminants in the groundwater to acceptable levels.

2.11.2 Compliance With ARARS

The selected remedial action will comply with all applicable or relevant and appropriate requirements. A complete listing of location-, action-, and chemical-specific ARARs, attained by each selected alternative, are included in Tables 2-14 through 2-16.

2.11.3 Cost-Effectiveness

The selected alternatives are cost-effective because they have been determined to provide overall effectiveness proportional to their costs. The selected alternatives are less costly than other alternatives, while providing a comparable level of protection, or they are expected to attain remedial goals in a shorter period of time while remaining comparable in cost to other alternatives.

2.11.4 Utilization of Permanent Solutions to the Maximum Extent Practicable

The Army has determined that the selected alternatives will offer the use of permanent treatment technologies to the maximum extent practicable while maintaining cost effectiveness. These alternatives provide long term protection to human health and the environment through removal, treatment or immobilization of the contaminated media. The USEPA and the Commonwealth of Virginia have reviewed and concurred with the selected remedy.

2.11.5 Preference for Treatment

The selected alternatives addresses the preference for treatment through groundwater recovery, air-stripping, and in-situ bioremediation. Contaminated soils excavated from the acid pits will

be treated utilizing thermal oxidation. In addition, capping of the landfill and placement of excavated soils in a RCRA C landfill will provide a reduction in mobility.

2.12 DOCUMENTATION OF SIGNIFICANT CHANGES

The preferred alternatives originally presented in the Proposed Plan are also the preferred alternatives selected in the Decision Document. The preferred alternative for OU-5 (Alternative 5-2) was modified to include carbon treatment of the air discharge after considering comments from the Alexandria Health Department. There have been no significant changes made to the remaining selected alternatives since the issuance of the Proposed Plan.

Table 2-1. Summary of Chemicals of Potential Concern at Cameron Station

Category	Chemical
Volatile Organic Compounds (VOCs)	1,2-Dimethylbenzene/o-xylene 1,3-Dimethylbenzene/m-xylene Acetone Benzene Carbon disulfide Ethylbenzene Methylisobutyl ketone Toluene Trichlorofluoromethane Xylenes, total combined
Semivolatile Organics	2,4-Dimethylphenol 2-Methylnaphthalene 2-Methylphenol/2-cresol Acenaphthene Anthracene Benzo[a]anthracene Benzo[a]pyrene Benzo[b]fluoranthene Benzo[g,h,i]perylene Benzo[k]fluoranthene Benzoic acid Bis (2-ethylhexyl) phthalate Chrysene Dibenz[a,h]anthracene Dibenzofuran Fluoranthene Fluorene Indeno[1,2,3-c,d]pyrene Naphthalene Phenanthrene Phenol Pyrene
Pesticides/Polychlorinated Biphenyls (PCBs) and Derivatives	2,2-Bis (para-chlorophenyl)-1,1,1-trichloroethane 2,2-Bis (para-chlorophenyl)-1,1-dichloroethane 2,2-Bis (para-chlorophenyl)-1,1-dichloroethene 2,4,5-Trichlorophenoxyacetic acid 2,4-Dichlorophenoxyacetic acid 2-(2,4,5-Trichlorophenoxy) propionic acid Aldrin

Table 2-1. Summary of Chemicals of Potential Concern at Cameron Station

Category	Chemical
Pesticides/Polychlorinated Biphenyls (PCBs) and Derivatives - continued	Alpha chlordane Beta-endosulfan/endosulfan II Dieldrin Endosulfan sulfate Endrin ketone Gamma-chlordane Heptachlor Heptachlor epoxide Lindane Methoxychlor PCB 1260
Chlorinated Dibenzo-p-dioxins	2,3,7,8-Tetrachlorodibenzo-p-dioxin/dioxin Total tetrachlorodibenzo-p-dioxins Total pentachlorodibenzo-p-dioxins Total hexachlorodibenzo-p-dioxins Total heptachlorodibenzo-p-dioxins Octachlorodibenzo-p-dioxin
Chlorinated Dibenzofurans	2,3,7,8-Tetrachlorodibenzofuran Total tetrachlorodibenzofurans Total pentachlorodibenzofurans Total hexachlorodibenzofurans Total heptachlorodibenzofurans Octachlorodibenzofuran
Inorganic Compounds[a]	Aluminum Arsenic Barium Beryllium Bromide Cadmium Chromium Cobalt Fluoride Lead Mercury Nickel Nitrate Nitrite Phosphate Silver Sulfate Thallium Vanadium

(a) Includes essential nutrients (e.g., hexavalent chromium) with reference doses or cancer slope factors.

OU-3 LANDFILL
CAMERON STATION
ALEXANDRIA, VIRGINIA

ALTERNATIVE	#1 NO ACTION	#2 SOIL CAPPING AND MONITORING THE LANDFILL
1.0 <u>Short Term Effectiveness</u>		
Protection of workers during remedial actions	Not applicable	Potential exposure during capping construction can be mitigated by personal protection and dust control.
Environmental impacts	Negligible	Increase in dust during construction of cap. Adequate controls can be implemented.
Time until action is completed (after ROD signing)	Existing risk remains	< 1 year

TABLE 2-9 (continued)
SUMMARY OF DETAILED ANALYSIS
OU-3 LANDFILL
CAMERON STATION
ALEXANDRIA, VIRGINIA

ALTERNATIVE	#1 NO ACTION	#2 SOIL CAPPING AND MONITORING THE LANDFILL
2.0 <u>Long-Term Effectiveness and Performance</u>		
Magnitude of residual risks	The residual risks to human health and the environment will be the same as the current risks.	Because landfilled materials do not pose a threat to human health or the environment, there will be minimal long-term residual risk associated with this alternative. A proper designed, constructed and maintained soil cap can provide long-term reliability.
Adequacy of control	Not applicable.	Soil capping is a well established technology. The soil cap will be effective in reducing direct exposure to landfilled wastes and leaching of contaminants.
Reliability of control	Not applicable.	Likelihood of failure is small as long as regular O&M is performed.

TABLE 2-9 (continued)
SUMMARY OF DETAILED ANALYSIS
OU-3 LANDFILL
CAMERON STATION
ALEXANDRIA, VIRGINIA

ALTERNATIVE	#1 NO ACTION	#2 SOIL CAPPING AND MONITORING THE LANDFILL
3.0 Reduction of Toxicity, Mobility or Volume, (TMV)	No reduction in TMV	Will not result in a reduction in toxicity or volume. The cap would indirectly reduce contaminants mobility, by reducing the potential for leaching.
4.0 Implementability		
Technical feasibility	Not applicable.	Capping is relatively easy to implement.
Administrative feasibility	Not applicable.	Generally administratively feasible.
Availability of services and materials	Not applicable.	Services and materials are readily available. Materials to contstruct cap are assumed to be available locally.
5.0 Cost (Present Worth 10-yr @ 5%)	$0	$96,400

CAMERON STATION
ALEXANDRIA, VIRGINIA

ALTERNATIVE	#1 NO ACTION	#2 GROUNDWATER COLLECTION FOLLOWED BY AIR STRIPPING SYSTEM AND DISCHARGE TO SURFACE WATER	#3 GROUNDWATER COLLECTION FOLLOWED BY LIQUID PHASE CARBON ABSORPTION AND DISCHARGE TO SURFACE WATER
2.0 Long-Term Effectiveness and Performance			
Magnitude of residual risks	The long-term risk to human health and the environment would be the same as the current risk. The groundwater contamination is projected to migrate further downgradient.	No long-term residual risk will be associated with the treated groundwater by the air stripping system.	No long-term residual risk would remain from organic conaminants adsorbed to GAC because spent carbon will be thermally regenerated off-site.
Adequacy of control	Not applicable.	Methods employed are generally conventional and effective.	Methods employed are generally conventional and effective.
Reliability of controls	Not applicable.	Groundwater extraction and air stripping treatment are adequate and reliable methods of remediating volatile organic contaminated groundwater.	Groundwater extraction and carbon adsorption treatment are adequate and reliable methods of remediating volatile organic contaminated groundwater.
3.0 Reduction of Toxicity, Mobility or Volume, (TMV)	No reduction in TMV	The air stripping system will effectively remove contaminants from groundwater but will not reduce the toxicity, mobility or volume of contaminants.	Volume and mobility reduction would be achieved by concentrating organic contaminants on the carbon surface. Toxicity reduction would also be achieved if the carbon was thermally regenerated thereby destroying the contaminants.

ALTERNATIVE	#1 NO ACTION	#2 GROUNDWATER COLLECTION FOLLOWED BY AIR STRIPPING SYSTEM AND DISCHARGE TO SURFACE WATER	#3 GROUNDWATER COLLECTION FOLLOWED BY LIQUID PHASE CARBON ABSORPTION AND DISCHARGE TO SURFACE WATER	#4 GROUNDWATER COLLECTION FOLLOWED BY AIR STRIPPING AND IN-SITU BIOREMEDIATION
2.0 Long-Term Effectiveness and Performance				
Magnitude of residual risks	The long-term risks to human health and the environment will be the same as the current risk. The contaminated ground-water is projected to migrate downgradient.	Long-term risk associated with the treated groundwater will be reduced by the air stripping system.	Spent carbon will be regenerated off-site, therefore no long-term risks will be associated with this alternative.	In-situ microbial reactions will convert organic contaminants into simpler and less toxic compounds, thus eliminating the long-term risks associated with contaminated groundwater.
Adequacy of control	Not applicable.	Methods employed are generally conventional and effective.	Methods employed are generally conventional and effective.	Under optimum operational conditions, methods employed are generally effective.
Reliability of controls	Not applicable.	Groundwater extraction and air stripping treatment are adequate and reliable methods of remediating volatile organic contaminated groundwater.	Groundwater extraction and carbon adsorption treatment are adequate and reliable methods of remediating volatile organic contaminated groundwater.	With the exception of unpredictable microbial activity, methods employed are relatively reliable with a low probability of failure.

TABLE 2-13 (continued) SUMMARY OF DETAILED ANALYSIS

3.1 OVERVIEW

The public reaction to the preferred alternatives during the public comment period was positive although one commenter recommended that the Army consider Alternative 5-3 instead of 5-2 for OU-5. Only three people had questions or comments regarding the Proposed Plan during the public comment period.

3.2 BACKGROUND AND COMMUNITY INVOLVEMENT

General community interest in Cameron Station has been minimal. Army and Federal regulations require public involvement in the RI/FS process. As a result, community interviews were conducted in August 1992. A total of 18 persons throughout the local community were interviewed through the use of a questionnaire. Information obtained from the interviews was used to develop a Public Involvement and Response Plan.

Notices of public comment period were placed in four local newspapers on March 4 and April 15, 1993. The comment period to review the Proposed Plan was established from March 4, through April 3, 1993. The comment period was ultimately extended an additional 30 days to May 3, 1993 at the request of a commenter.

3.3 SUMMARY OF PUBLIC COMMENTS AND AGENCY RESPONSE

The following is a summary of the questions/comments raised during the 60-day public comment period and how the Army has addressed these issues:

(1) The Alexandria Health Department requested that the 30-day public comment period be extended.

Army response: The comment period was extended 30 additional days.

(2) In addition, the Health Department wanted the Army to reconsider

(2) In addition, the Health Department wanted the Army to reconsider the use of Alternative 5-2 for OU-5 and replace it with Alternative 5-3. They were concerned about volatiles being released to the air during the treatment of the contaminated groundwater.

Army response: The U.S. Army Environmental Center (USAEC) forwarded a letter of response to the Health Department indicating that the Army had reconsidered and would change the method of cleanup to Alternative 5-3. Subsequent to that letter, it was determined that the same level of protectiveness would be achieved by adding carbon treatment to the air discharge from the Alternative 5-2 air stripper, while still providing a cost savings over Alternative 5-3. The USAEC discussed this option and received the Health Department's concurrence that Alternative 5-2 with the addition of carbon treatment of the air discharge would be selected.

(3) Commenter wanted to know how to place a bid to perform restoration.

Army response: USAEC informed commenter to call a point of contact at the Baltimore District Corps of Engineers since they would be performing all remediation at Cameron Station.

(4) Commenter wanted to know if USAEC could conduct a public meeting and focus on redevelopment.

Army response: USAEC informed commenter that a public meeting could be held, however only environmental issues presented in the Proposed Plan would be discussed. Commenter was given a point of contact at the office of Director of Planning and Community Development for the City of Alexandria and also the real estate point of contact for the Baltimore District Corps of Engineers to discuss redevelopment issues. Commenter no longer requested a public meeting.

(5) Commenter stated that all environmental risks associated with the contamination

at Cameron Station should be eliminated and that cleanup of contamination should be performed according to regulatory standards.

Army response: USAEC forwarded a letter to the commenter assuring this person that all remediation would be conducted according to applicable regulatory cleanup standards and performed consistent with the approach defined in the Proposed Plan.

APPENDIX A

GLOSSARY

APPENDIX A
GLOSSARY

Applicable or Relevant and Appropriate Requirements (ARARs): The federal and state requirements that a selected remedy must attain. These requirements may vary among sites and alternatives.

Benzene: A volatile organic compound associated with gasoline; also used as a solvent.

Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), or Superfund: A federal law passed in 1980 and modified in 1986 by the Superfund Amendments and Reauthorization Act. The Act created a trust fund, known as Superfund, to investigate and cleanup abandoned or uncontrolled hazardous waste sites.

Decision Document (DD): A document that describes the final remedial actions selected for a site, why the remedial actions were chosen and others not, how much they will cost, and how the public responded.

1, 2-Dichloroethane: A volatile organic compound associated with solvents; sometimes used as a gasoline additive.

Groundwater: Water found beneath the earth's surface in geologic formations that are fully saturated. When it occurs in sufficient quantity, groundwater can be used as a water supply.

Interim Remedial Action (IRA): An agreement between the State Agency and the owner(s) of a site for rapid response action to control or reduce the spread of contamination.

Operable Unit: A portion of a site that has been conceptually separated from the rest of the site to allow for easier management.

Polychlorinated Biphenyls (PCBs): A semi-volatile organochlorine compound used in dielectric fluids for their insulating and non-degradational properties.

Present Worth: A term used to indicate the discounting of sums to be received in the future to their present value equivalent, or the amount which will accumulate to that sum if invested at assumed interest rates.

Remedial Design (RD): Preparation of plans and specifications so that the selected remedial actions for a site can be constructed or implemented.

Remedial Investigation/Feasibility Study (RI/FS): A two-part study of a hazardous waste site that supports the selection of a remedial action for a site. The first part, the RI, identifies the nature and extent of contamination at the site. The second part, the FS, identifies and evaluates alternatives for addressing site contamination.

Trichloroethene: A volatile organic compound commonly associated with solvents.

Volatile Organic Compounds (VOCs): Organic liquids that readily evaporate under atmospheric conditions. Example compounds include trichloroethene (TCE) and benzene.

Summary of PM10 Air Concentrations at Exposure Points[a]

Exposure Point	Exposure Scenario	Ann. Ave. PM10, kg/m3
Cameron Lake	Current Future	4.7E-09 4.7E-09
Gas Station (Bldg. 23)	Current	4.1E-09
Picnic Ground	Current Future	1.3E-08 1.3E-08
Ballfield	Current Future	3.7E-08 3.7E-08
Jogging Trail from Service Road	Current Future	5.2E-07 5.2E-07
Jogging Trail from Landfill	Current Future	3.8E-08 3.8E-08
Bldg. 30 Soil Area	Current Future	2.2E-08 NA[b]
Construction Site	Current Future	NA 2.4E-08

(a) The estimated PM10 air concentration is multiplied by the mass fraction of the chemical of potential concern to obtain the air concentration of the chemical.
(b) NA = Not applicable.

Box Model Estimations of VOC Air Concentrations Emitted From Subsurface Soils

Chemical	Estimated Air Concentrations, kg/m3			
		Cameron Lake		
	Gas Station	Current	Future	Future Residence
Acetone	6.1E-15	5.9E-15	6.0E-14	5.9E-14
Benzene	4.3E-17	4.1E-17	4.2E-16	4.1E-16

(a) Future yard and construction work area soil are represented by rail line soils only. Construction site air concentration (1.3E-12 mg/m^3) is product of PM10 air concentration and dioxin equivalent soil concentration.

Risk Calculation for Benzene and Trichloroethylene (TCE)
in Air at Future Yards

Parameter	Units	South Plume Benzene	North Plume TCE
Predicted Air Concentration	mg/m^3	1.2E-10	1.3E-10
Human Intake Factors for Inhalation Route:			
Residential Adult Lifetime	m^3/kg-day	9.4E-02	9.4E-02
Residential Child Lifetime	m^3/kg-day	8.8E-02	8.8E-02
Inhalation Dose:			
Residential Adult Lifetime	mg/kg-day	1.2E-11	1.2E-11
Residential Child Lifetime	mg/kg-day	1.2E-11	1.2E-11
Inhalation Slope Factor	$(mg/kg\text{-}day)^{-1}$	2.9E-02[(a)]	6.0E-03
Cancer Risk Estimates:			
Residential Adult Lifetime	Unitless	3.4E-13	7.4E-14
Residential Child Lifetime	Unitless	3.2E-13	6.9E-14

APPENDIX D

GLOSSARY OF EVALUATION CRITERIA

APPENDIX D
GLOSSARY OF EVALUATION CRITERIA

Overall protection of human health and environment addresses whether or not a remedy provides adequate protection and describes how risks posed through each pathway are eliminated, reduced, or controlled through treatment, engineering controls, or institutional controls.

Compliance with ARARs addresses whether or not a remedy will meet all of the applicable or relevant and appropriate requirements of federal and state environmental statues and/or provide grounds for invoking a waiver.

Long-term effectiveness and permanence refers to the magnitude of residual risk and the ability of a remedy to maintain reliable protection of human health and the environment over time once cleanup goals have been met.

Reduction of toxicity, mobility, or volume through treatment is the anticipated performance of the treatment technologies that may be employed in a remedy.

Short-term effectiveness refers to the period of time with which the remedy achieves protection, as well as the remedy's potential to create adverse impacts on human health and the environment during the construction and implementation period.

Implementability is the technical and administrative feasibility of a remedy, including the availability of materials and services needed to implement the chosen solution.

Cost includes capital, operation and maintenance, and present worth costs.

State acceptance of the preferred alternative will be addressed in the Decision Document after the public comment period ends.

Community acceptance will be addressed in the Decision Document following a review of the public comments received on the RI/FS report and the Proposed Plan.
